ENTERPRISE STORAGE STACK

ESS Can Reduce the Cost of Using Samsung SM843T and TN SSDs

The Samsung SM843T series of SSD is a well respected Enterprise SSD. The 843T is built with 20,000 erase cycle endurance Flash, six times the endurance of Flash commonly used in Commercial grade SSDs.

Samsung advertises that the 843TN will accept 11 overwrites per day for five years if used in linear write mode and 1.4 overwrites per day if used in random write mode. This is a wear amplification level of about 8:1.

The T variant of the drive creates a larger reserve pool equal to about 17% of the visible flash (the difference between 960GB and 800GB of addressable flash). The T series has a wear life of 5.5 overwrites a day and a wear amplification of about 2:1.
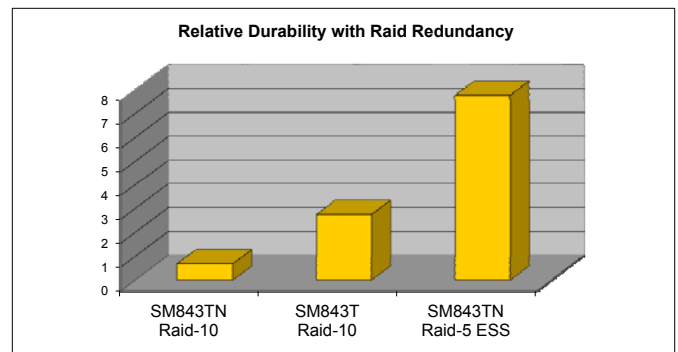

Samsung 843TN drives are affordably priced. For instance, shopping on Google shopping, 960GB drives cost as little as $1,028. Similarly, our understanding is that the T series has the same effective cost per device: which would be $1,028 for an 800GB 843T SSD.

Enterprise Storage Stack is a block filter which converts randomly written IO into atomic FIFO linear writes bounded on both erase block and Raid-stripe boundaries.
As a result, intrinsic wear amplification is typically <1.3:1. Similarly, ESS is extremely fast. Writes occur at the linear write speed of the device, which is about five times the random write speed of the device.

When used with a Raid-set, the advantages of ESS increase. Because ESS writes only linearly, it avoids the 2x raid amplification
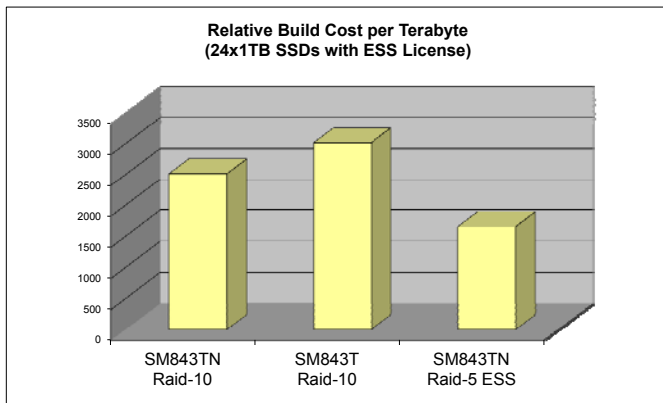

inherent in both Raid-5 and Raid-10, reducing raid amplification to $1/_{(n-1)}$. In large 24 SSD Raid-5 arrays, ESS can almost halve wear, and more than halve it for high security Raid-6 sets.

Relative Durability with Raid Redundancy

Similarly, ESS when used with a Raid-5 set will perform much faster. 24 843T SSDs, managed by Linux Raid-5 will only write about 30,000 IOPS – which is normally an unacceptable performance for Flash appliances. The same media, Raid-10, will only deliver 180,000 write IOPS. But the ESS managed Raid-5 set will deliver far in excess of a million write IOPS.

24 Drive Relative Random Write Performance (IOPS)

But what is most compelling, as the following table shows, is that while ESS delivers more durability in terms of total writes per day as well as radically greater random write speed, ESS delivers these capabilities in our basic topology at significantly lower total cost … in some cases halving manufacturing costs.

The possible cost savings and benefits do not end with our basic engine.

Our Enhanced Engine adds a number of both useful and cost-saving capabilities.

On the durability side, these include checksums and micro stripes. Checksums assure that all read and written data is correct, while micro stripes permit the intelligent repair of damaged data. These durability elements enhance durability elements already present in the basic product, such as the soundness of never overwriting existing data, and of writing FIFO to assure data continuity.
ESS's deduplication and compression engine is designed to create space efficiencies real time. The entire advanced engine, including appropriate compression and deduplication, normally writes at levels above a million IOPS.

Similarly, the advanced engine uses a virtual memory approach to reduce the amount of RAM required, and conversely to permit the construction of very large systems. With enhanced ESS, it is possible to build systems addressing a hundred terabytes of physical Flash, with logical addressing approaching a petabtye.

Compression commonly increases physically addressable space by a factor of two. In ordinary usage, Deduplication will improve space utilization by a further 15% to 20%. In VDI and similar environments, deduplication can reduce physical storage requirements by a factor of 5x to 10X.

The following table shows the relative cost of usable space if we assume that deduplication and compression can at least double addressable space. In such an environment, ESS systems with M550 SSDs become six times less expensive than 843T's used in a generic manner. In such an environment, ESS based systems utilizing SM843T SSDs become as much as four times less expensive than the same hardware used in a generic manner.

While enhanced ESS cuts manufacturing costs per terabyte even further, it also improves media life by reducing the amount of data written to the media either through compression or the virtualization of deduplication. Accordingly, a 2x increase in logical space utilization decreases total wear by a factor of two, while increasing the number of supportable daily overwrites by a factor of two.
